

Stellar UV versus cosmic-ray electrons at $z=10$: Salpeter against a top-heavy IMF

Top-heavy IMF: Jeong, Jeon, Song & Bromm (2025) eq. (2), $\xi(m) \propto m^{-1.3}$ on $1\text{-}100 M_{\odot}$, stated for Pop II at $z=10$.
 K_{UV} : Salpeter 1.15×10^{-28} (Madau & Dickinson 2014 eq. 10); top-heavy obtained by applying their $\eta_{\text{UV}} = 3.57 \times 10^{28}$ ratio, i.e. $\times 0.2801$.
CAVEAT CARRIED FROM THE SOURCE: that η_{UV} is derived from an EXTREME (Pop III-like) IMF in Zackrisson+11, not from the $\alpha=1.3$ law - Jeong et al. state this themselves.
 ξ_{ion} and ρ_{UV} are held fixed: both are measured, so the stellar channel is IMF-independent and panels (a) and (b) show ONE orange curve.
